1. Introduction

1.1 Terms of Reference

Ground Investigation Limited has been commissioned by PKA Architects Limited, acting on behalf of QSIL Metals UK Limited (the Client), to carry out a Phase 1 Assessment of Land Quality in the context of a proposed new extension to their premises at 15 Porte Marsh Road in Calne, Wiltshire. The scope of works for the assessment has been discussed and agreed with the Architects and Client.

This report incorporates a desk-based preliminary geo-environmental risk assessment, together with a preliminary geotechnical appraisal of the ground conditions in the context of foundation design and construction. It presents the findings of the desk-based research, together with preliminary consideration of the likely geo-environmental and geotechnical issues which could affect the proposed development of the site, based on the historical, geological and environmental data examined.

The preliminary risk assessment (PRA) presented within this report is expected to be submitted to the Local Authority in the context of the planning application for the proposed development.

1.2 Site Location

The site comprises the Client's industrial unit and associated yard area which is located on the western side of Porte Marsh Road on Porte Marsh Industrial Estate in Calne. The approximate National Grid reference at the centre of the site is E400170, N172060, and its postcode is SN11 9BN.

A recent topographic survey drawing provided by the Client's Architect has been used as the base to Figure 1.

More detailed information concerning the site interior and its boundaries is included within Section 2.3 of this report, based on a site walkover.

1.3 Proposed Development

The proposed development is expected to comprise the refurbishment of the northern unit and construction of a new two-storey extension to its southern elevation. The new extension will replace a previous southern unit, which was damaged by fire in early 2025, and will occupy a similar footprint to the old structure, which had been partially demolished by the time of this report.

The new extension will house factory plant and equipment on the ground floor, together with offices, canteen, conference rooms, and other ancillary accommodation spaces at first floor level.

1.4 Objectives and Scope of Work

The main objectives of the study undertaken are summarised as follows:

- (i) Examine factual historical, geological and geo-environmental data relating to the site and its immediately surrounding area.
- (ii) Identify potentially significant geo-environmental and geotechnical hazards on the basis of the information examined.

- (iii) Provide a preliminary assessment of the potential risk from ground contamination in the context of the site history and proposed development.
- (iv) Provide preliminary guidance concerning geotechnical conditions and discuss the potential foundation options for the proposed development.
- (v) Make recommendations for further intrusive investigatory works where appropriate.

1.5 Report Structure

This report is presented in five sections, the contents of which are summarised below:

- **Section 1** introduces the report and identifies the site location, summarises the proposed development, and outlines the objectives of the study and the general scope of work.
- **Section 2** presents the sources of information consulted and summarises the findings of the desk-based research, including a site description based on information gathered during a walkover survey.
- **Section 3** considers the findings of the desk-based research in the context of potential geo-environmental hazards affecting the proposed development.
- **Section 4** considers the anticipated ground conditions at the site in the context of the engineering design and construction of the proposed development.
- **Section 5** makes recommendations for the further intrusive investigatory works necessary to provide information for engineering design purposes, and to assess potential geo-environmental hazards at the site.

2. Data Sources, General Information & Description

2.1 General

The desk study has examined information relating to the historical and present-day land uses in the vicinity of the site, together with geological, hydrogeological and environmental conditions from a variety of sources. This section of the report identifies the principal sources of data that have been consulted.

The information furnished by this desk study is referred to in subsequent sections where it is significant, or has relevance, to consideration of the various issues addressed by this report.

2.2 Sources of Information

The principal sources of information consulted by the desk study are summarised as follows.

- | | | |
|-------|--------------------------------------|--------------|
| (i) | Present-day Ordnance Survey mapping. | (Ref. 1) |
| (ii) | Geological mapping. | (Ref. 2) |
| (iii) | Google Earth historical imagery. | (Ref. 3) |
| (iv) | Historical Ordnance Survey mapping. | (Appendix A) |
| (v) | Landmark Geology Report. | (Appendix B) |
| (vii) | Landmark Envirocheck Report. | (Appendix C) |

2.3 Site Description

A site walkover was undertaken by an experienced geologist from GI on 14th October 2025 to supplement the findings of the desk-based research. Significant observations made during the walkover are noted below.

The study site is roughly rectangular in plan, extending to an area of c.0.3 hectares with maximum dimensions of c.65 m north-south by c.60 m east-west. The site is elevated at around 80 m AOD according to present-day Ordnance Survey mapping and features a very gentle fall to the west.

The site is occupied by the existing manufacturing unit with a concrete surfaced yard area that wraps around the northern and western elevations of the building and, until recently, included two small areas of managed soft landscaping along its eastern periphery.

A fire broke out at the premises in early 2025 and caused extensive damage to the southern portion of the factory, which originally comprised two single-storey buildings of steel portal-framed construction with brick masonry infill and sheet metal cladding. The two buildings were formerly linked by a central flat roof structure (which apparently included bitumen roof felt). Both buildings include large flues and cleanser units adjacent to their northern and southern elevations respectively.

At the time of the walkover, the northern building had been refurbished, whilst the central link and southern fire-damaged element had been largely demolished, save for a small section at its rear in which production continued, and a two-storey brick and asbestos-sheet cladded extension to the west elevation that houses a water tank. The soft landscaped areas in the east of the site were stripped in the context of these works.

The northern part of the existing yard was set up as a temporary storage compound for contractors undertaking the demolition and refurbishment works. The old slab for the southern unit remained in-situ and new drainage runs were being cut in. These excavations had exposed a thin veneer of concrete slab construction and Made Ground over natural, brownish or greenish grey clay soils; these materials as well as building rubble were being temporarily stockpiled on the slab. Standing water was evident within the trenches, following recent rainfall.

Various chemical, waste and bulk gas storage areas were evident within the west of the service yard, including hydrogen and nitrogen tanks. Process water from the electroplating is pumped to an effluent pit to the rear of the northern unit, where the pH is balanced prior to discharge into the drain to the west of the site. Waste chemicals, such as potassium ferricyanide, are stored in a below-ground bund to the south of the fire-damaged unit before being transferred to intermediate bulk containers (IBCs) for off-site disposal; whilst acid waste is pumped directly into IBCs. Used nickel filters and other solid materials are placed in bins prior to removal from site.

It is understood that the Client liaised with the Environment Agency (EA) during the fire in the context of the potential for firefighting foam to enter the drain to the west of the site via drainage holes within the service yard's perimeter wall. The drainage holes were plugged to stop firefighting residues entering the drain and the resultant foam / liquid residues were subsequently cleaned up via a vacuum tanker and removed from site.

Direct vehicular access to the site is directly from Porte Marsh Road to the east, with a self-storage facility, food wholesaler and tyre seller opposite the site. The eastern boundary is currently enclosed by Heras fencing, whilst post and mesh fences form the northern and southern boundaries along with a blockwork wall to the west. Beyond the site boundaries is a vehicle testing centre (north), an electrical components manufacturer (south) and a school (west). The wider industrial estate, which extends further eastwards includes various other commercial and industrial enterprises, located within a 100 m radius of the study site.

The nearest surface water feature is the drain to the west of the site, of which the only visible section appeared to be dry at the time of the walkover. At the specific point close to the northwest of the site, the watercourse was brick-lined and featured a man-made level change where it entered a culvert.

Notwithstanding the chemical and waste stores referred to above, no obvious bulk storage facilities for fuel or oil were noted during the site walkover. External areas were inspected for any staining associated with leaks or spillages, but no visible or olfactory evidence was noted.

Probable asbestos-containing materials (ACMs) were observed forming the cladding to the first floor level of the water tank structure; it should be acknowledged that the consideration of ACMs within the existing building fabric is beyond the scope of this report.

Selected photographs illustrating the observations made during the site walkover are presented in Appendix D.

2.4 Historical Ordnance Survey Mapping

Previous land uses, as inferred from an examination of the historical Ordnance Survey (OS) mapping (Appendix A), together with other information in the public domain, are summarised below:

- The earliest published Ordnance Survey (OS) mapping, dated 1886, indicates that the site is predominantly open, agricultural land at this time. A tributary of Abberd Brook is present around 2 m west, flowing southwards from a pond some 150 m northwest. The hamlet of

Calne Marsh is around 100-150 m east, including a large pond c.90 m east, and Calne Marsh Brick Works, together with a clay pit and possible above ground tanks c.225 m southeast.

- On the 1900 map edition, the site remains undeveloped. The brick works to the southeast has expanded in a southerly direction, and four ponds are evident within the old workings, whilst a small terrace of houses has been constructed opposite.
- The 1924 map iteration shows no significant changes have occurred on-site. Further residential development has occurred in the vicinity of the brick works however, which appears to have ceased operations; several of the smaller ponds have been infilled and new terraced housing constructed over non-extractive areas of that site.
- The site and immediately surrounding land still remain in agricultural use according to the 1936 map edition. This continues to be the case for the subsequent post-war aerial imagery included with the mapping, which dates from 1950 and shows that linear residential development extending along Oxford Road to join the housing at the old brickworks. Further development is also evident on the northeastern periphery of Calne, remote to the south.
- The first post-war small-scale map edition, dated 1960, suggests the site remained unaltered. The northward expansion of residential areas continued further south, however, with housing around 400 m southwest.
- A printed circuit works has been constructed on-site by 1969, which comprises the present-day northern manufacturing unit, and an electricity substation has been erected on the southern boundary. Porte Marsh Road forms the eastern boundary with warehousing beyond and the current vehicle testing centre is also present to the north. Some 90 m northeast is a rubber and plastics factory, whilst further warehouses, a clothing factory and a scrap metal yard are beyond 100 m southeast. Housing now extends to around 55 m southwest.
- The early 1980s mapping indicates that the works building on-site has been expanded to its current extent. Several unspecified factories and depots have been constructed on land immediately south, whilst a mill is shown c.120 m north.
- By 1994, it appears that the present effluent pit has been erected to the rear of the northern unit. Porte Marsh Industrial Estate now extends beyond 250 m north.
- Google Earth aerial imagery dating from 1999 up to present-day shows the site relatively unchanged, however, within the wider commercial / industrial setting, some infill development of formerly vacant plots is evident, as is the extensive residential development which extends northwards along the western and eastern flanks of the industrial estate.

In summary, the site originally comprised agricultural land until the development of the Porte Marsh Industrial Estate, commencing in the 1960s, since when the site was occupied by a printed circuit works followed by its present-day electroplating usage. The immediately surrounding area shares a similar history with several potentially contaminative uses noted within a 100 m radius of the study area.

2.5 Geology

The following information relating to the geology of the site has been obtained from multiple sources, including the relevant British Geological Survey (BGS) geological sheet (Ref. 2), the Landmark Geology Report and the Envirocheck Report (Appendices B and C), as summarised below:

- Both the geological mapping sheet and the Geology Report indicate the site to be directly underlain by the Kimmeridge Clay Formation of Jurassic age; which is described by the BGS as: “*Mudstones (calcareous or kerogen-rich or silty or sandy); thin siltstone and cementstone beds; locally sands and silts.*”
- No Made Ground or superficial deposits are mapped on-site; however, some Made Ground or disturbed ground is anticipated given the site’s earlier development history. It should be noted in this context that where such artificial deposits are relatively thin, or of low areal extent, they would not be expected to be recorded on mapping of the scale indicated. Given the presence of a tributary of Fisher’s Brook is adjacent to the west, some Alluvial soils could be encountered along this margin of the site.
- The Envirocheck Report indicates that the site lies within an area unlikely to be affected by coal mining. In this regard, no Coal Measures strata would be expected to underlie the site within the possible depth of influence of the surface.
- There are several BGS recorded mineral sites within the wider area, the closest of which were old clay pits at the former Calne Marsh Brick Works, some 335 m southeast. That site has been redeveloped and presumably the pits would have been infilled prior to development, however no Worked or Made Ground is indicated in these areas on the basis of the geological mapping.
- No man-made or natural cavities are reported within influencing distance of the study site.
- According to the Envirocheck Report, the property lies within a lower probability radon area, such that there is no statutory requirement for the inclusion of radon protection measures within the construction of new dwellings and extensions. The same would be expected to apply to a commercial extension of the type proposed. Further consideration is provided in subsequent sections of this report with regards to other potentially hazardous ground gases.
- Based on the available geological mapping, the site is indicated to be underlain by ground conditions which could give rise to low hazard potential from shrinking / swelling clays. The hazard potential for other ground stability issues including ground dissolution, running sands, compressible or collapsible ground and landslides, is given as either very low or negligible. Based on previous experience of the type of deposits underlying the study area, weathered Kimmeridge Clay soils could be classified as highly plastic.
- The Kimmeridge Clay Formation is identified by the BRE (Ref. 4) as potentially containing elevated levels of pyrite. Any superficial deposits or Made Ground may contain elevated pyrite and / or sulphate depending on their origin.

2.6 Hydrology, Hydrogeology and Environmental Setting

Key points from the Envirocheck Report (Appendix C) relating to the hydrology, hydrogeology and environmental setting of the site are summarised as follows:

- A bedrock aquifer designation of Unproductive Strata is ascribed to the underlying Kimmeridge Clay Formation, and the site is not located within any groundwater source protection zones (SPZs).
- There is a single licence held by Aggregate Industries UK Limited for the abstraction of groundwater for use as process water from an excavated pit / storage lagoon, although the data point reference appears to be erroneously given as 137 m west, which relates to a domestic

property. The nearest potable water abstraction is recorded some 735 m east and operated by an L. M. Noad with groundwater abstracted from a well for domestic use; this is unlikely to be sensitive to contamination from the site area acknowledging the anticipated low permeability deposits below the site and distance to the abstraction.

- The nearest significant surface water feature is a tributary of Abberd Brook, around 2 m west, flowing in a southerly direction. The stream / drain has been culverted locally, but is exposed at the ground surface adjacent to the site.
- The Envirocheck Report indicates that the site is not situated within a floodplain nor is it in an area with the potential for groundwater flooding to occur, according to BGS flood data. Further consideration of the risk or consequence of flooding is not within the scope of this report.
- A historic consent for the discharge of process effluent into the Abberd Brook tributary was held by Southern Valley Feeds Limited, who produced food and dairy products at Porte Marsh Mill, 147 m northwest of the study site. The consent was revoked in July 2009.
- No pollution incidents to controlled waters are reported within an 800 m radius of the site.
- No historic or existing licensed landfills are reported within a 500 m radius of the site. The Envirocheck dataset lists Calne Sandpit as the closest former landfill site, c.595 m northeast, which accepted inert, industrial / commercial and household waste up until December 1990. The closest waste facility to the study area was a materials recycling facility operated by Hills Waste Solution Limited, c.90 m southeast; the licence was surrendered in September 2011.
- Calne Peak Power Electricity Generation Facility located on Clarke Avenue and operated by Conrad (Calne) Limited, 123 m east, is listed as an Environment Agency integrated pollution prevention and control site with an effective permit for medium-sized combustion plant. Humphrey Feeds Limited, operating from Porte Marsh Mill, holds an effective permit for the treatment of raw animal and vegetable materials for the production of food stuffs.
- Two active permits included on the list of Local Authority pollution prevention and control sites are held by Tamura Europe Limited for coating of metal and plastic, located on Clarke Avenue around 87 m northeast, and Safety First Commercial Limited for a waste oil burner, located on Penhill Industrial Estate, c. 245 m east.
- Acknowledging the site's location within an industrial estate, numerous commercial and industrial enterprises are listed on the trade directory with active listings for haulage and distribution services, tyre dealers, a recycling service, a metal products fabricator, railway equipment / electrical components / sound equipment systems manufacturers, concrete products supplier, precision engineers, automotive repairs, an injection moulding (plastics) specialist and a pest control company within a 250 m radius of the study site. The closest fuel station entry is Calne Service Station, 390 m south.
- No sensitive land use areas are shown within proximity to the study site.

3. Geotechnical Considerations

3.1 General

This section of the report considers the ground conditions in the context of the engineering design and construction of the new extension and provides preliminary guidance concerning the design of foundations and ground floor slabs, based on the information provided by the initial desk-based research.

Based on the likely presence of in-situ natural cohesive soils at shallow depth and perhaps only modest thickness of Made Ground, as indicated by the recent excavations on-site, it is expected that it should be possible to utilise traditional spread foundations for the proposed development, where new foundations are required.

Within ground conditions of this type, where natural soils are present at shallow depth, excessive consolidation settlement is unlikely to be a significant factor. However, the potential influence of any nearby trees or vegetation, including new planting, given the anticipated plastic nature of the underlying soils would require consideration when determining appropriate foundation depths.

Differential settlement could be a factor where new foundations span between strata of differing compressibility, e.g. natural soils, Made Ground or even onto old foundations. In this context, it is likely that the existing foundations are within homogeneous materials, acknowledging that the refurbished section of the building did not exhibit any obvious signs of structural distress. It will be important, however, to consider the potential for differential settlement of new construction to occur relative to the remaining parts of the building. The interface between the existing structure and new extension will need to be designed accordingly to ensure that any minor differential movement does not result in structural or cosmetic damage.

Given the above, several geotechnical factors relating to the site and underlying ground conditions will influence the design and construction of any new foundations and ground floor slabs. These factors will need to be addressed by appropriate intrusive investigatory works, necessary to provide the detailed information required for design purposes.

It is possible, however, on the basis of the findings of the desk-based research completed, to make some preliminary comments concerning the geotechnical aspects of the proposed works.

3.1.1 Excavations

Based on the desk-based research, it is anticipated that the site is likely to be underlain by a modest thickness of hard surfaced construction and Made Ground, followed by natural, cohesive deposits of the weathered Kimmeridge Clay at shallow depth, which could be locally reworked or disturbed in proximity to existing structures.

The shallow Made Ground and weathered Kimmeridge Clay would generally be expected to be excavated using conventional plant, albeit with a potential requirement for breaking equipment to penetrate hard construction and / or remove obstructions, such as remnant foundations or other buried masonry obstructions.

The Made Ground deposits have the potential to be heterogeneous, comprising a mix of particle sizes, which could lead to problems with excavation stability or overbreak where coarser constituents are removed from the trench sides by the physical action of excavation.

Excavations within shallow subsoils would be expected to be battered back to a suitably shallow angle of repose to be assessed based on the findings of the intrusive investigation, however, special care will need be taken to avoid undermining adjacent foundations and thereby the stability of neighbouring structures.

Consideration may need to be afforded to the control of perched groundwater or possible contamination, acknowledging the site's long-standing manufacturing history and recent fire damage, subject to the findings of the intrusive investigation.

3.1.2 Foundations and Ground Floor Slabs

As discussed above, beneath a modest thickness of Made Ground, the site is likely to be underlain by shallow cohesive soils of the Kimmeridge Clay Formation.

Given the above, it is considered that traditional spread foundations are likely to be appropriate to support new loadings. It is anticipated that new strips or pads would be taken down through any Made Ground and founded within the underlying natural subsoils at relatively shallow depth, however, determination of foundation depths and precautions in respect of ground heave would need to take into consideration the plastic nature of the underlying soils in the context of the potential influence of trees.

Spread foundations would need to be designed by an experienced and suitably qualified engineer who should select appropriate design parameters and working loads based on the findings of the subsequent intrusive investigation.

Assurances would need to be sought from prospective contractors concerning the potential environmental impact of the works, including reference to the potential for vibration or displacement damage to any nearby structures during demolition or groundworks, particularly if founded on shallow footings. In this regard, it may be prudent to consider whether any underpinning works could be required.

Given the likely underlying ground conditions, the use of either ground-bearing or suspended ground floor slabs, the latter with an appropriately dimensioned underfloor void, could be utilised for traditional building types, subject to the findings of an intrusive investigation. In this regard, however, it should be noted that suspended ground floor slabs could be a more secure option where shrinkable near-surface soils are present. Moreover, as a consequence of previous construction within the development footprint there is expected to be some Made Ground and/or disturbance associated with earlier substructures. As such, acknowledging the likely disturbance to the formation, a suspended floor slab may ultimately be considered the most secure option.

It should be noted that the site does not lie within a radon affected area, therefore there is no statutory requirement for protection measures to be included within the ground slab design.

Intrusive investigatory works will be required to confirm the underlying shallow depth ground conditions and inform the design of traditional foundations. It should be appreciated in this context, however, that the encountered ground conditions could differ to those indicated on the BGS mapping, whereby, for example, Alluvium could encroach into the site area, and/or deep Made Ground could be revealed. In such circumstances consideration would need to be afforded to alternative solutions, for example including deeper piled foundations.

3.1.3 External Areas

Any new pavements should be engineered on the basis of the intrusive investigation findings, making reference to CBR test data, incorporating an appropriate sub-base thickness and sufficient articulation to mitigate surface deterioration, together with any influence on their drainage characteristics.

It should be appreciated that differential settlement could potentially occur across localised hard spots, for example associated with earlier foundations or other substructures.

3.1.4 Drainage

No details have been provided with regards to the proposed drainage strategy for the new extension. However, given the presence of low permeability deposits underlying the site, it is unlikely that soakaway drainage would be an option for surface water disposal.

In this context, it seems likely that the strategy could involve the re-use of the existing drainage infrastructure on-site.

Subject to engineering advice and the approval of the regulators, the most practical solution may be to connect the new surface water drainage system to the existing public sewer network.

3.1.5 Conclusion

Potential geotechnical issues relating to the presence of shrinkable soils, together with Made Ground and disturbance associated with existing subsurface construction could influence the depth and type of foundation required for the development. Moreover, it cannot be discounted that the ground conditions could vary from those suspected on the basis of this initial desk study. Such factors will need to be addressed and fully evaluated based on the findings of a comprehensive and detailed intrusive ground investigation.

4. Potential Geo-Environmental Hazards

4.1 Introduction

It is appropriate to consider the findings of the desk-based research using a risk assessment approach, consistent with the requirements of the LCRM framework (Ref. 5), whereby a conceptual site model is developed, on the basis of the relationship between potential contamination sources, pathways and receptors, taking into consideration the available information concerning the site history, geology, hydrology, hydrogeology and environmental setting.

This section of the report provides a preliminary assessment of the level of risk posed by ground contamination in the context of the proposed new extension, based on the findings of the initial desk-based research.

It will be necessary for the preliminary conceptual site model described in the following section to be extended and refined in light of the findings of the subsequent intrusive investigatory works and laboratory analyses.

4.2 Preliminary Conceptual Site Model

4.2.1 Possible Sources of Contamination

It is possible to make the following comments in relation to possible sources of contamination at the site on the basis of the desk-based research and site inspection undertaken.

- The earliest available historic mapping indicates the site was in agricultural use until the development of Porte Marsh Industrial Estate from the 1960s onwards, with the site being occupied by a printed circuit works, prior to the present-day electroplating works.
- The main drivers for considering potential risks from ground contamination are related to the industrial legacy of the study site, which presently handles a variety of chemicals, including acids and heavy metals in the context of the electroplating processes. It should also be appreciated, however, as noted in Section 2.0 above and further considered below, that the surrounding district has a long-established legacy of industrial land use and diffuse sources of contamination exist in the area.
- Potential contaminants of concern would include a wide range of elements and compounds such as trace metals, heavy metals, asbestos, inorganic or organic compounds and petroleum hydrocarbons.
- Moreover, the recent fire at the site could have resulted in a range of fine combustion products being produced together with potential contamination caused by firefighting foam. In this context whilst the foam was historically acknowledged as a significant potential source of highly mobile PFAS compounds, their use has been largely phased out and banned since 2011, with further restrictions put in place in the current year on generally smaller scale sources such as fire extinguishers etc, and where the foam can be contained and collected. Notwithstanding the above, as discussed in Section 2.0, it is understood that the Client liaised with the EA during the fire and measures were enacted to prevent firefighting foam from entering the drain to the west with the resultant foam / liquid residues reportedly collected using a vacuum tanker and removed from site.

- Asbestos containing materials (ACMs) are understood to be present within part of the existing building, which is to be demolished, but also their degradation or any uncontrolled localised removal or demolition historically could have resulted in the liberation of fibres and subsequent migration into the site's subsoils. This would be mitigated, however, by the extensive hard surfacing.
- The anticipated shallow depth of Made Ground and underlying mapped geology are unlikely to represent a significant source of hazardous ground gases.
- The site lies within proximity to many existing and historic commercial and industrial land uses, acknowledging its location on an industrial estate, such as a vehicle testing centre, a mill, factories, warehousing, engineering works or depots, for example, which could possibly have led to elevated potential contaminants of concern within the locality. An electricity substation is present on the southern boundary.
- No large-scale migratory ground gas sources, such as historic landfills or other infilled groundworkings, are present within influencing distance. Furthermore, the site is located within a lower probability radon area.

4.2.2 Receptors of Contamination and Migration Pathways

4.2.2.1 Receptors

The following potentially sensitive human health and environmental receptors should be considered for a development of the type proposed, making reference to the accompanying desk-based research:

- Future site users, including the visitors and staff of the premises.
- Site construction and maintenance workers.
- The general public and occupiers of neighbouring land, including users of the adjacent roads, footpaths and surrounding residential properties.
- The underlying groundwater (albeit considered to be of low sensitivity given that the Kimmeridge Clay Formation is classified as unproductive strata).
- Nearby surface water features, notably the drain / tributary of Abberd Brook, immediately adjacent to the west.
- Buried concrete or water supply pipes.

4.2.2.2 Pathways

The following potential contaminant migration pathways would ordinarily be considered for a development of the type proposed:

- Inhalation of airborne particulate matter or vapours from contaminated soil in outdoor or indoor air.
- Ingestion of contaminated soil or groundwater directly, by deliberate consumption, indirectly, by for example eating or smoking with dirty hands, and by ingestion of fugitive dust.

- Dermal contact with contaminated soil or groundwater, possibly leading to absorption of contaminants into the body through the skin, and / or causation of skin conditions such as dermatitis.
- Leaching of water infiltrating through contaminated soils, which can transport soluble contaminants into groundwater.
- Migration of contaminated groundwater either laterally or vertically, dependent on the permeability of the ground, together with other factors such as the presence of preferential pathways and / or man-made voids, e.g. along service trenches.
- Migration of ground gases or volatile hydrocarbon vapours either laterally or vertically through permeable or voided ground and accumulation within unprotected buildings.
- Damage to building materials by direct contact with aggressive ground conditions, or in association with its coastal setting, for example sulphate attack on concrete and / or hydrocarbon attack on plastics, e.g. water supply pipes.

4.3 Preliminary Risk Assessment - Conclusions

4.3.1 Context

This preliminary assessment considers potential soil contamination risks associated with the proposed extension on the basis of the findings of this desk-based research.

It should be noted that the northern unit is to be retained and refurbished with some internal alterations, and a new two-storey extension constructed on its southern elevation (to replace the fire-damaged, and now partially demolished, southern unit). This will be coupled with upgrades to the hard surfacing which will encapsulate the underlying Made Ground and will remove the source-receptor linkage with regards to the dermal contact and ingestion pathways across much of the site. Whilst local changes to hard surfacing type may be installed around the building periphery, in addition to providing new car parking bays along the eastern boundary, it is understood that some limited soft landscaping may potentially be retained in this area.

The exact internal layouts are unknown at the time of writing, and whilst process areas are likely to feature large, well-ventilated, open plan spaces at ground floor level to account for new plant and machinery, some smaller enclosed areas are likely to be present.

4.3.2 Potential Chronic Human Health Risks

The Made Ground deposits are considered the most significant possible source of potential contaminants of concern. However, as discussed above, the site surface will be largely encapsulated by the existing building and by new ground floor slab construction of the new extension, together with upgrading any hardstanding areas.

Due to the refurbishment and retention of the northern unit and the new extension effectively replacing the old southern unit, together with any hard surfacing being upgraded, significant chronic human health risks resulting from dermal contact with, or ingestion of, contaminated soils will not arise across much of the site. However, in the east of the site, whilst some new parking is proposed, it is likely to be interspersed with new soft landscaping, therefore a limited dermal / ingestion exposure pathway remains in this area.

In general, however, across the existing building footprint the only remaining plausible pathway is the inhalation of indoor air, which will need to be addressed in the context of the subsequent investigatory works.

In conclusion, in respect of chronic human health risks arising from the presence of contaminated soils following completion of the proposed development, acknowledging the aforementioned considerations, in general, it is unlikely that significant further risks will be realised when compared to the site as existing.

4.3.3 Potential Acute Human Health Risks

The potential for acute human health risks to impact on the construction workforce, together with the general public and occupiers of surrounding properties should be considered in the context of the pre-construction health and safety plan prepared by the building or groundworks contractor.

Whilst potential acute human health risks are currently mitigated by the hard surfaced construction of the service yard and existing floor finishes, as will also be the case on completion of the development, it should be appreciated that the replacement of the existing hard surfacing and / or any penetrations required for new foundations, other groundworks and drainage engineering works, could expose underlying potentially contaminated soils. This should be taken into consideration in the specification of appropriate PPE and it should be ensured that effective suppression of particulate matter is put in place during any earthworks activities.

Given the likely age of the fill material, if present, and historic development on-site, the potential presence of asbestos within any Made Ground soils cannot be discounted, and any bulk soil handling operations should be treated with care. Indeed, it is understood that there are ACMs have been used for the cladding to the upper level of the structure housing the water tank, which is intended for demolition. Particular consideration will need to be afforded accordingly to the demolition of this structure and subject to an asbestos survey an appropriately licensed contractor utilised if required.

4.3.4 Potential Risks from Hazardous Ground Gases

Considering potential ground gas sources on-site, the Made Ground, if present, is expected to be modest in thickness such that the degradation of putrescible or organic materials therein would not be capable of producing a significant volume of hazardous ground gas. In this regard, direct visual inspection of the soils exposed in trench faces around the proposed new extension did not indicate any such materials to be present, therefore the Made Ground is anticipated to present a negligible risk of gas generation.

The same conclusion can be drawn for the underlying natural strata, based on visual observation within the recently excavated trenches, thus such soils would be unlikely to contribute to an onerous ground gas regime.

There is the potential that the ongoing service yard and car park usage in the north of the site could give rise to hotspot contamination associated with the leakage or spillage of fuel or oils from vehicles and potentially associated with the maintenance of process equipment inside the building. Whilst these mobile hydrocarbons would eventually degraded over time and the volatile compounds lost, there remains the potential for some residual hydrocarbon contamination to remain in the soils on-site, which could pose a limited vapour risk to occupiers of the refurbished and extended building.

Based on the Envirocheck Report, the site lies within a lower probability radon area, such that there is no statutory requirement for the inclusion of a radon barrier as part of the new ground floor slab construction.

Acknowledging the industrial heritage of the area, it would be a prudent precaution to afford some further consideration to potential ground gas risks. This could initially be completed on a qualitative basis, however, making reference to the encountered ground conditions and any associated evidence of hydrocarbon contamination.

4.3.5 Potential Risks to Controlled Waters

As discussed above, the Kimmeridge Clay deposits underlying the study area are deemed to be unproductive strata due to the low permeability nature of the geological formation, therefore the groundwater at the site is not sensitive from a controlled waters perspective, and there are no potable water abstractions within influencing distance of the study site.

Whilst the proposed development will require the construction of new foundations, acknowledging the site's elevation, location and the anticipated ground conditions, it is unlikely that these would be deep enough to intersect the groundwater table or create significant new preferential migration pathways for mobile contaminants, as would be the case with other deeper foundation solutions, such as piling.

Therefore, the critical controlled waters receptor in the context of the site's development is the surface watercourse immediately west of the site. The drain appeared to be dry at the time of the walkover, having originally been fed by a pair of ponds further northwards which are no longer shown on present-day OS mapping, and is culverted along much of its length where it adjoins the study site. As such, it is anticipated that the drain is unlikely to be in hydraulic connectivity with any slowly percolating groundwater within the Kimmeridge Clay.

In the above context, any mobile contamination entering the ground on-site is likely to be held within any granular Made Ground horizons at the boundary with the low permeability Kimmeridge Clay soils. Whilst this could potentially be mobilised by infiltrating perched water with lateral migration towards the drain, this mechanism is reliant on there being a continuous fairly permeable stratum of Made Ground being present and deficiencies in the culvert wall, which seems unlikely.

Given the on-site treatment of process effluent and careful handling and off-site disposal of other waste products, together with the low permeability soils underlying the site, there appears to be a low likelihood of a migration pathway for any contamination arising from ongoing site processes.

The new extension / ongoing industrial use of the site does constitute a potentially contaminative land use; upgrades to existing surface water drainage infrastructure and the provision of new or resurfaced ground slabs are likely to provide a degree of environmental betterment in the context of the proposed development.

On the above basis it is considered that potential risks to controlled waters associated with the refurbishment works are low and, subject to the findings of the initial intrusive investigations, are unlikely to warrant more detailed quantitative assessment.

5. Recommended Intrusive Investigatory Works

5.1 General

It will be necessary to supplement this desk-based research with a suitable Phase 2 intrusive ground investigation in order to provide the geotechnical information necessary for design purposes, together with an appropriate level of assessment of potential contamination risks.

5.1.1 Geotechnical Investigation

Several investigative techniques could be suitable in order to provide information for foundation design purposes, given the anticipated shallow depth of natural soils, with the exploratory holes to extend down through the hard surfaced construction and Made Ground into the underlying variably weathered deposits of the Kimmeridge Clay Formation.

In this regard, small diameter dynamically sampled boreholes formed using a tracked Archway Dart rig would be an efficient method of gaining information relating to the shallow depth soils to around 5.0 m depth with disturbed samples recovered in plastic liners. The drilling would be commenced from the base of hand excavated inspection pits to mitigate the potential risk to buried utilities and Standard Penetration Tests (SPTs) would typically be undertaken at regular intervals within the boreholes to confirm the strength / density of the soils and enable bearing capacity and ground floor slab design to be considered.

This would be preferable to the excavation of trial pits using a mechanical excavator or similar, which whilst being a cost-effective method of obtaining such information, would create a greater degree of ground disturbance and pose more of a risk to buried services.

It should be noted that this drilling technique may refuse on, or be deflected by, buried obstructions, and would not penetrate the competent bedrock, although the latter is not anticipated within the depth of investigation.

Samples should be collected from the boreholes for laboratory tests to confirm engineering parameters for design purposes, including for example, classification tests to establish soil plasticity.

5.1.2 Contamination Assessment

Potential contamination risks from any Made Ground and other deposits could be assessed concurrently with the geotechnical investigation works detailed above, as representative samples could be recovered from the window sampler boreholes for chemical testing.

The boreholes sunk during the investigation could also be installed with ground gas / groundwater monitoring wells and a regime of monitoring put in place, which would not be the case for machine dug trial pits. This would be unlikely to be necessary, however, if shallow Made Ground is present, as is envisaged may be the case.

Samples of the encountered soils and / or groundwater recovered from the boreholes should be submitted to a UKAS accredited laboratory for chemical analysis.

Scheduling of the laboratory analyses should take into consideration both the physical findings of the intrusive investigatory works and the desk-based research described in this report, affording particular consideration to the presence of the types of Made Ground material present. Depending on the investigation findings, the analytical suite would be expected to include an extensive range of

chemical contaminants, including, for example, metals, PAHs, TPHs, PFOS, PFOA, cyanide, sulphate and pH, together with asbestos screening.

Further, more extensive testing or detailed assessment could be required subject to the investigation findings and consideration by the Local Authority regulators in the context of the planning system.

Ordnance Survey Plan

Published 1960

Source map scale - 1:10,000

The historical maps shown were reproduced from maps predominantly held at the scale adopted for England, Wales and Scotland in the 1840's. In 1854 the 1:2,500 scale was adopted for mapping urban areas; these maps were used to update the 1:10,560 maps. The published date given therefore is often some years later than the surveyed date. Before 1938, all OS maps were based on the Cassini Projection, with independent surveys of a single county or group of counties, giving rise to significant inaccuracies in outlying areas. In the late 1940's, a Provisional Edition was produced, which updated the 1:10,560 mapping from a number of sources. The maps appear unfinished - with all military camps and other strategic sites removed. These maps were initially overprinted with the National Grid. In 1970, the first 1:10,000 maps were produced using the Transverse Mercator Projection. The revision process continued until recently, with new editions appearing every 10 years or so for urban areas.

Large-Scale National Grid Data

Published 1994

Source map scale - 1:2,500

'Large Scale National Grid Data' superseded SIM cards (Ordnance Survey's 'Survey of Information on Microfilm') in 1992, and continued to be produced until 1999. These maps were the fore-runners of digital mapping and so provide detailed information on houses and roads, but tend to show less topographic features such as vegetation. These maps were produced at both 1:2,500 and 1:1,250 scales.

Geology 1:50,000 Maps

This report contains geological map extracts taken from the BGS Digital Geological map of Great Britain at 1:50,000 scale and is designed for users carrying out preliminary site assessments who require geological maps for the area around the site. This mapping may be more up to date than previously published paper maps.

The various geological layers - artificial and landslip deposits, superficial geology and solid (bedrock) geology are displayed in separate maps, but superimposed on the final 'Combined Surface Geology' map. All map legends feature on this page. Not all layers have complete nationwide coverage, so availability of data for relevant map sheets is indicated below.

Artificial Ground and Landslip

Artificial ground is a term used by BGS for those areas where the ground surface has been significantly modified by human activity. Information about previously developed ground is especially important, as it is often associated with potentially contaminated material, unpredictable engineering conditions and unstable ground.

Artificial ground includes:

- Made ground - man-made deposits such as embankments and spoil heaps on the natural ground surface.
- Worked ground - areas where the ground has been cut away such as quarries and road cuttings.
- Infilled ground - areas where the ground has been cut away then wholly or partially backfilled.
- Landscaped ground - areas where the surface has been reshaped.
- Disturbed ground - areas of ill-defined shallow or near surface mineral workings where it is impracticable to map made and worked ground separately.

Mass movement (landslip) deposits on BGS geological maps are primarily superficial deposits that have moved down slope under gravity to form landslips. These affect bedrock, other superficial deposits and artificial ground. The dataset also includes foundered strata, where the ground has collapsed due to subsidence.

Superficial Geology

Superficial Deposits are the youngest geological deposits formed during the most recent period of geological time, the Quaternary, which extends back about 1.8 million years from the present.

They rest on older deposits or rocks referred to as Bedrock. This dataset contains Superficial deposits that are of natural origin and 'in place'. Other superficial strata may be held in the Mass Movement dataset where they have been moved, or in the Artificial Ground dataset where they are of man-made origin.

Most of these Superficial deposits are unconsolidated sediments such as gravel, sand, silt and clay, and onshore they form relatively thin, often discontinuous patches or larger spreads.

Bedrock and Faults

Bedrock geology is a term used for the main mass of rocks forming the Earth and are present everywhere, whether exposed at the surface in outcrops or concealed beneath superficial deposits or water.

The bedrock has formed over vast lengths of geological time ranging from ancient and highly altered rocks of the Proterozoic, some 2500 million years ago, or older, up to the relatively young Pliocene, 1.8 million years ago.

The bedrock geology includes many lithologies, often classified into three types based on origin: igneous, metamorphic and sedimentary.

The BGS Faults and Rock Segments dataset includes geological faults (e.g. normal, thrust), and thin beds mapped as lines (e.g. coal seam, gypsum bed). Some of these are linked to other particular 1:50,000 Geology datasets, for example, coal seams are part of the bedrock sequence, most faults and mineral veins primarily affect the bedrock but cut across the strata and post date its deposition.

Combined Surface Geology

The Combined Surface Geology map combines all the previous maps into one combined geological overview of your site.

Please consult the legends to the previous maps to interpret the Combined "Surface Geology" map.

Additional Information

More information on 1:50,000 Geological mapping and explanations of rock classifications can be found on the BGS website. Using the LEX Codes in this report, further descriptions of rock types can be obtained by interrogating the 'BGS Lexicon of Named Rock Units'. This database can be accessed by following the 'Information and Data' link on the BGS website.

Introduction

The Environment Act 1995 has made site sensitivity a key issue, as the legislation pays as much attention to the pathways by which contamination could spread, and to the vulnerable targets of contamination, as it does the potential sources of contamination. For this reason, Landmark's Site Sensitivity maps and Datasheet(s) place great emphasis on statutory data provided by the Environment Agency/Natural Resources Wales and the Scottish Environment Protection Agency; it also incorporates data from Natural England (and the Scottish and Welsh equivalents) and Local Authorities; and highlights hydrogeological features required by environmental and geotechnical consultants. It does not include any information concerning past uses of land. The datasheet is produced by querying the Landmark database to a distance defined by the client from a site boundary provided by the client. In this datasheet the National Grid References (NGRs) are rounded to the nearest 10m in accordance with Landmark's agreements with a number of Data Suppliers.

APPENDIX D

Photographs

Plate 1

P2079.15 Porte Marsh Road, Calne.
Northern unit, with soft landscaped areas stripped long eastern elevation.

Plate 2

P2079.15 Porte Marsh Road, Calne.
Bulk gas storage and cleanser with flues adjacent to the northern elevation of northern unit.

Plate 3

P2079.15 Porte Marsh Road, Calne.
Interior of the recently refurbished northern unit.

Plate 4

P2079.15 Porte Marsh Road, Calne.
Service yard area in north of site with temporary compound for groundworks contractor.

Ground Investigation

www.ground-investigation.com

Plate 5

P2079.15 Porte Marsh Road, Calne.

Remaining fire-damaged section of southern unit with metal plates covering chemical waste bund (centre left of image).

Plate 6

P2079.15 Porte Marsh Road, Calne.

Remnant ground slab from southern unit penetrated by new service trenches, including recent scarring from the re-directed electricity supply.

Plate 7

P2079.15 Porte Marsh Road, Calne.
Greenish grey soils of the weathered Kimmeridge Clay exposed within base of trench.
Standing water result of recent rainfall.

Plate 8

P2079.15 Porte Marsh Road, Calne.
Chemical storage area to rear of southern unit.

Ground Investigation

www.ground-investigation.com

Plate 9

P2079.15 Porte Marsh Road, Calne.
Suspected asbestos containing materials within cladding to structure housing water tank.

Plate 10

P2079.15 Porte Marsh Road, Calne.
Bulk gas storage in southwest of service yard.

Plate 11

P2079.15 Porte Marsh Road, Calne.
Numerous IBCs of de-ionised and de-mineralised water within the service yard.

Plate 12

P2079.15 Porte Marsh Road, Calne.
Water treatment tanks and effluent pit to rear of northern unit.

Ground Investigation

www.ground-investigation.com

Plate 13

P2079.15 Porte Marsh Road, Calne.
Process water in the effluent pit.

Plate 14

P2079.15 Porte Marsh Road, Calne.
The drain to the west of the site falling into culvert at bottom left. The drain appears to be dry at the time of the walkover.
